

Appendix: Automated Estimates of State Interest Group Lobbying Populations

Alex Garlick

Assistant Professor of Political Science, The College of New Jersey, email: garlicka@tcnj.edu

John Cluverius

Assistant Professor of Political Science, University of Massachusetts Lowell, email: John_Cluverius@uml.edu

This appendix accompanies the article published in *Interest Groups & Advocacy*. First, it describes the data collection process for this project. Next, it relates the code books from the different data sources. Then it has details on the different iterations of the automated method, and reports the results from each iteration. It also has an example of the bootstrap procedure described in the main text. Finally, it lists the stop words that are omitted from the bags of words.

Data collection

The first layer of data for this project is a census of the businesses, non-profits and governments that hire lobbyists in all 50 states from the National Institute for Money in State Politics (NIMSP). The NIMSP data is available to the public on its website,¹ although we were provided with the underlying data through 2017.² There are 2.07 million observations between 2000 (although national coverage picks up in 2006) through 2017 in this list.

Table 6 describes how the data sources used to build the estimates described in Section 2 were acquired. Table 6 shows the number of unique group registrations in each data source over time.

Table 6: Data sources for lobbying group registrations

Venue	Years	Source	No. of Codes
Colorado	2005-2014	CD-ROM from Sec. of State, also at: sos.state.co.us/lobby/Home.do	31
Massachusetts	2005-2016	Scraped from Sec. of State sec.state.ma.us/LobbyistPublicSearch/	26
Pennsylvania	2007-2018	Downloaded from Dept. of State palobbyingservices.state.pa.us/	42
All 50 States	2007	Gray and Lowery Team (GL 2007)	26
All 50 States	2005-2017	ZIP file from NIMSP, also at: followthemoney.org/lobbyist-link	350

Mapping subject codes

The GL 2007 codes assign each organization to one of 26 sectors (Lowery et al., 2012, p.596). The last column of Table 6 shows how many industry codes are used in the different states. Tables

¹e.g. Illinois 2011 directory followthemoney.org/lobbyist-link?s=IL&y=2011

²We thank Peter Quist and Denise Roth Barber at NIMSP for supplying their source files that is surfaced at classic.followthemoney.org/database/search.phtml.

Table 7: Group registrations by year: 2005-2018

Year	Colorado	Massachusetts	Pennsylvania*	GL 2007	NIMSP
2005	1,093	1,036			17,640
2006	1,130	1,046			48,612
2007	1,150	1,067		51,061	50,093
2008	1,173	1,138	426		50,123
2009	1,200	1,221			46,857
2010	1,167	1,352	471		47,068
2011	1,280	1,355			49,255
2012	1,245	1,360	493		42,539
2013	1,336	1,406			54,941
2014	1,231	1,440	405		52,594
2015		1,437			57,920
2016		1,368	417		56,390
2017					54,161
2018			1,872		
Total	12,005	12,077	4,082	51,061	628,733
Average	1,201	1,006	681	51,061	48,364

*Penn. only reports groups in their latest lobbying period, therefore groups are observed once.

8 & 9 align those codes to the GL 2007 codes. In many cases the alignment is clear: 'Health care' in Pennsylvania corresponds to the GL 2007 'Health' code. However, these pathways can be muddled. Therefore, we use the Policy Agenda Project's codebook as a crosswalk, specifically the version written for the Pennsylvania Policy Agendas Project (McLaughlin et al., 2010)³ that is sensitive to state-level issues, and include the appropriate major or minor codes in the second column of Table 8.

There are two important features of the subject codes to note in Tables 8 & 9. First, there are gaps. For example, Massachusetts does not have a category for Agriculture. This does not mean there are no dairy farmers in Massachusetts, just that the state apparently did not think there were enough to populate a category; as a result, they probably file as a business association and organization. Second, the bottom of Table 8 lists all of the unused subject categories for the legislative venues. There is a general 'business' category in all of these states, however, the GL 2007 coding scheme does not have such a broad category, so these extra-broad delineations are dropped. The 350 NIMSP codes were mapped to the PAP scheme using the GL 2007 coding scheme (Lowery et al., 2012).

Table 10 relates the GL 2007 codes to Holyoke (2019). Holyoke puts groups in 17 economic sectors, which do not neatly align with the GL codes. As a result, there is a higher degree of measurement error when comparing the aggregate totals from this scheme than when the automated estimates are compared to the GL estimates (in Figure 1).

³This version of the Comparative Agendas Project is hosted by Temple University: <http://www.cla.temple.edu/papolicy/>.

Testing the Method

This section tests the estimates produced the method, specifically evaluating 36 iterations of the estimation procedure on two different sets of testing data. First, I will note the alternative specifications used to create the myriad iterations.

1. Create 6 sets of ‘bags of words’ for each policy sector S , by observing the full distribution of words with three different source materials.
 - (a) Use the GL 2007 hand coded list as source material.
 - (b) Use the GL 2007 hand coded list as source material, with the stop words in Table 15-18 removed.
 - (c) Use the 2006-2018 Colorado and Pennsylvania lobbying registrations as source material.
 - (d) Use the 2006-2018 Colorado and Pennsylvania lobbying registrations, with the stop words in Table 15-18 removed.
 - (e) Use the GL 2007 hand coded list and 2006-2018 Colorado and Pennsylvania lobbying registrations as source material.
 - (f) Use the GL 2007 hand coded list and 2006-2018 Colorado and Pennsylvania lobbying registrations as source material., with the stop words in Table 15-18 removed. The posterior probabilities built off these ‘bags of words’ are listed in Table 11.
2. There are no alternative specifications for estimating the posterior probabilities, or the likelihood of a word falling in a policy sector. Of note, the posterior probabilities are defined for each set of ‘bags of words’ listed in step 1.
3. There are two different equations to estimate the conditional probability P_c that each word k in a document fits each policy sector.
 - (a) The standard method takes the raw count of words in each bag.

$$P_{c,k} = \frac{N_{c,k}}{N_s} \quad (1)$$

- (b) The *Laplace* method conducts a Laplace smoothing procedure by adding one for each quantity, this eliminates zeroes (so that logarithms may be taken).

$$L_{c,k} = \frac{(N_{c,k} + 1)}{N_s} \quad (2)$$

4. There are three different equations to combine the conditional probabilities of the words in each document.
 - (a) Products:

$$P_c = \prod_{i=1}^k P_{c,k} \quad (3)$$

(b) Log: Note that this equation uses the Laplace smoothing procedure for each word.

$$P_c = \sum_{i=1}^k \log(L_{c,k}) \quad (4)$$

(c) Means

$$P_c = \frac{\sum_{i=1}^k P_{c,k}}{k} \quad (5)$$

5. There is only one method to estimate the Bayes probability of each class by multiplying the conditional probability for each policy sector by the sector's posterior probability.

$$B_s = P_c \times P_s \quad (6)$$

6. There are two different types of bootstraps used to randomly draw a single class for each document. After sorting the Bayes estimates in a descending fashion for each document that has $1 \geq k \leq 26$ non-zero Bayes estimates, the methods vary in V , or the number of potential classes they keep. They also vary in how much the Bayes estimates are weighted in the random draw procedure. See Table 12 for examples of both.

(a) Coinflip Bootstrap: For $0 > V \leq 2$, inclusive of ties, each bootstrap draws an unequal probability sample, proportional to B_s .

(b) Weighted Bootstrap: For $0 > V \leq 5$, inclusive of ties, each bootstrap draws an unequal probability sample, proportional to B_s^2 .

Example Bootstrap

Table 12 demonstrates the bootstrap procedure for the document estimated in Table ???. Column (1) shows an example of a 'coinflip' bootstrap, while column (2) shows a weighted bootstrap. Table 12 shows the Bayes estimates produced by the 'Log' estimation procedure to demonstrate a document with a large number of potential policy areas is reduced down by the bootstrap procedures.

Optimizing the algorithm

A researcher could argue for any one of 36 iterations above. This section evaluates each iteration twice, first on a test set of the codes provided in the NIMSP data. While there is no pattern to the missingness in these data, there is no reason to believe the codes that are present are biased, therefore they provide a reasonable set to test estimates produced by the automated procedure. It also uses data from Massachusetts. As a reminder, Schütze, Manning and Raghavan (2008, p. 154-155) suggest that these methods should be judged by its precision and retrieval. Precision is the share of estimations that are correct. Recall is the share of possibly relevant documents that are retrieved. They suggest balancing these two criteria by calculating an F1-score, which is the weighted harmonic mean of precision and recall show in equation ???. where P is precision, and R is recall.

Table 11: Posterior probabilities for the 26 policy areas using stop words

	Policy Sector	Words in bag	Posterior Probability
1	Health	15,389	0.133
2	Education	11,251	0.097
3	Banking	9,274	0.080

8	8	Manufacturing	0.0139					
9	9	Social Welfare	0.0120					
10	9	Small Business	0.0120					
11	11	Business Services	0.0120					
12	12	Sports/Rec.	0.0095					
13	13	Legal	0.0060					
14	13	Tax	0.0060					
15	13	Environment	0.0060					
16	13	Communications	0.0060					
17	13	Utilities	0.0060					
18	13	Hotel/Ent.	0.0060					

Notes:

- (1) The top two Bayes estimates (with ties) are kept.
(2) STATA randomly selects a sector using the Bayes estimate as an analytic weight.
(3) Up to 5 estimates are kept, inclusive of ties.
(4) The Bayes estimate is squared (B_s^2).
(5) STATA randomly selects a sector using the squared Bayes estimate as an analytic weight.

Tables 13 and 14 show the performance of each iteration of the model on the two out-of-sample tests. The procedure used in the main text had the highest average F1-score across the two models. It was the second highest performing model under both tests. It used both the GL 2007 codes, as well as the Colorado and Pennsylvania lobbying registrations as the source for the bags of words and posterior probabilities. It also used the 1557 ‘stop words’ and used the ‘weighted’ bootstrap method. Each of these methods was tested over 50 bootstraps.

The F1 levels shows in Table 14 are lower than in Table 13; however, this discrepancy is due to the lack of alignment between the number of categories Massachusetts offers groups (23) and the 26 hand-codes. There were a number of uncoded groups in Table 9 that do not map onto the Massachusetts coding scheme, and some of the codes that do match are not exhaustive.

List of Stop Words

Tables 15, 16, 17, and 18, list the 1557 stop words that were excluded from the bag of words calculation. This list was created by highlighting words that were prominent in multiple bags but did not differentiate the type of groups effectively.

Notes (1) (2) (3) (4) (5) (6)

(1) Average matches from 50 bootstrap draws.

(2) There are 5,219 unique group names in the Mass. database.

(3) There are 1557 stop words in Table 15-18.

(4) Source for bags of words. Hand-coded (H), Colorado, Pennsylvania.

(5) Methods: Log, Products, Means.

(6) Bootstrap type: Coin flip or weighted.
